

## DATA SHEET

### NAME OF MEDICINE

BETAGAN<sup>®</sup> eye drops (levobunolol hydrochloride), 2.5mg/mL or 5mg/mL

### PRESENTATION

Clear, colourless to slightly yellow, sterile ophthalmic solution.

### USES

#### *Actions*

Levobunolol (HCl) is a noncardioselective  $\beta$ -adrenoceptor blocking agent, equipotent at both  $\beta_1$  and  $\beta_2$  receptors. Levobunolol HCl is greater than 60 times more potent than its dextro isomer in its  $\beta$ -blocking activity, yet equipotent in its potential for direct myocardial depression. Accordingly, the levo isomer, levobunolol HCl, is used. Levobunolol HCl does not have significant local anaesthetic (membrane stabilising) or intrinsic sympathomimetic activity.

The primary mechanism of the ocular hypotensive action of levobunolol hydrochloride (HCl) in reducing IOP appears to be a decrease in aqueous humor production. BETAGAN<sup>®</sup> eye drops reduce IOP with little or no effect on pupil size or accommodation in contrast to the miosis which cholinergic agents are known to produce. The blurred vision and night blindness often associated with miotics would not be expected and have not been reported with the use of BETAGAN<sup>®</sup> eye drops. This is particularly important in cataract patients with central lens opacities who would experience decreased visual acuity with pupillary constriction.

$\beta$ -adrenergic receptor blockade reduces cardiac output in both healthy subjects and patients with heart disease. In patients with severe impairment of myocardial function,  $\beta$ -adrenergic receptor blockade may inhibit the stimulatory effect of the sympathetic nervous system necessary to maintain adequate cardiac function.

$\beta$ -adrenergic receptor blockade in the bronchi and bronchioles results in increased airway resistance from unopposed parasympathetic activity. Such an effect in patients with asthma or other bronchospastic conditions is potentially dangerous.

BETAGAN<sup>®</sup> eye drops (levobunolol HCl) have been shown to be an active agent in lowering elevated as well as normal intraocular pressure (IOP), whether or not accompanied by glaucoma. Elevated IOP presents a major risk factor in glaucomatous field loss. The higher the level of IOP, the greater the likelihood of optic nerve damage and visual field loss.

The onset of action with one drop of BETAGAN<sup>®</sup> eye drops can be detected within one hour after treatment, with maximum effect seen between 2 and 6 hours. A significant decrease in IOP can be maintained for up to 24 hours following a single dose.

### ***Pharmacokinetics***

Nil

### ***Indications***

Control of intraocular pressure in patients with open angle glaucoma.

Control of ocular hypertension.

Treatment of acute increased intraocular pressure following laser capsulotomy and extracapsular cataract extraction.

### **DOSAGE AND ADMINISTRATION**

The recommended starting dose is one drop of BETAGAN<sup>®</sup> 0.25% eye drops in the affected eye(s) twice a day. If clinical response is not adequate, dosage may be increased to one drop of BETAGAN<sup>®</sup> 0.5% eye drops in the affected eye(s) twice a day. Studies have also shown that IOP is controlled in many patients with one drop of BETAGAN<sup>®</sup> 0.5% eye drops in the affected eye(s) once a day. Careful monitoring of patients is advised, particularly in the first few days after starting treatment or if the dose of BETAGAN<sup>®</sup> eye drops is increased.

Dosages above one drop of BETAGAN<sup>®</sup> 0.5% eye drops twice daily are not generally more effective. If the patient's IOP is not at a satisfactory level on this regimen, concomitant therapy with dipivefrine and/or adrenaline, and/or pilocarpine and other miotics, and/or systemically administered carbonic anhydrase inhibitors, such as acetazolamide, can be instituted.

In order to minimise systemic absorption of BETAGAN<sup>®</sup> eye drops, apply pressure to the tear duct immediately following administration of the drug.

### ***Use in Children***

Safety and effectiveness in children have not been established.

### **CONTRAINDICATIONS**

BETAGAN<sup>®</sup> eye drops are contraindicated in those individuals with bronchial asthma or with a history of bronchial asthma or severe chronic obstructive pulmonary disease (see Warnings and Precautions); sinus bradycardia; sick sinus syndrome (including sino-atrial nodal block); second or third degree atrioventricular block; overt cardiac failure (see Warnings and Precautions); cardiogenic shock; or hypersensitivity to any component of this product (see Further Information).

### **WARNINGS AND PRECAUTIONS**

BETAGAN<sup>®</sup> eye drops should be used with caution in patients with known hypersensitivity to other  $\beta$ -adrenergic blocking agents. Use with caution in patients with known diminished pulmonary function.

In patients with angle-closure glaucoma, the immediate objective of treatment is to re-open the angle. This requires, in most cases, constricting the pupil with a miotic. BETAGAN<sup>®</sup> eye drops have little or no effect on the pupil. When BETAGAN<sup>®</sup> eye drops

are used to reduce elevated IOP in angle-closure glaucoma, it should be followed by a miotic and not used alone.

As with other topically applied ophthalmic drugs, BETAGAN<sup>®</sup> eye drops may be absorbed systemically. The same adverse reactions found with systemic administration of  $\beta$ -adrenergic blocking agents may occur with topical administration. For example, severe respiratory reactions and cardiac reactions, including death due to bronchospasm in patients with asthma, and rarely death in association with cardiac failure, have been reported with topical application of  $\beta$ -adrenergic blocking agents (see Contraindications).

The preservative in BETAGAN<sup>®</sup>, benzalkonium chloride, may be absorbed by soft contact lenses. BETAGAN<sup>®</sup> eye drops should not be used while wearing soft contact lenses. Patients should be instructed to remove lenses before instilling BETAGAN<sup>®</sup> eye drops and wait at least 15 minutes after instilling BETAGAN<sup>®</sup> eye drops before re-inserting their lenses.

**Cardiac Failure:** Sympathetic stimulation may be essential for support of the circulation in individuals with diminished myocardial contractility, and its inhibition by  $\beta$ -adrenergic receptor blockade may precipitate more severe failure.

BETAGAN<sup>®</sup> should be used with caution in patients with cardiovascular disease (e.g. coronary heart disease, Prinzmetal's angina and cardiac failure) and hypotension.

Due to its negative effects on conduction time, beta-blockers should only be given with caution to patients with first degree heart block.

#### **Vascular Disorders**

Patients with severe peripheral circulatory disturbance/disorders (e.g. Raynaud's phenomenon) should be treated with caution.

**Obstructive Pulmonary Disease:** Patients with mild/moderate chronic obstructive pulmonary disease should, in general, not receive beta blockers, including levobunolol; however, if levobunolol is deemed necessary in such patients, it should be administered with caution.

**In Patients without a History of Cardiac Failure:** Continued depression of the myocardium with  $\beta$ -blocking agents over a period of time can, in some cases, lead to cardiac failure. At the first sign of symptoms of cardiac failure, BETAGAN<sup>®</sup> eye drops should be discontinued.

**Non-allergic Bronchospasm:** In patients with non-allergic bronchospasm or with a history of non-allergic bronchospasm, (e.g. chronic bronchitis, emphysema), BETAGAN<sup>®</sup> eye drops should be administered with caution since they may block bronchodilation produced by endogenous and exogenous catecholamine stimulation of  $\beta_2$ -receptors.

**Major Surgery:** The necessity or desirability of withdrawal of  $\beta$ -adrenergic blocking agents prior to major surgery is controversial.  $\beta$ -adrenergic blockade impairs the ability of the heart to respond to  $\beta$ -adrenergically mediated reflex stimuli. Levobunolol may impair compensatory tachycardia and may augment the risk of

hypotension when used with general anaesthesia in surgical procedures. Some patients receiving  $\beta$ -adrenergic blocking agents have been subject to protracted severe hypotension during anaesthesia. For these reasons, in patients undergoing elective surgery, gradual withdrawal of  $\beta$ -adrenergic blocking agents may be appropriate. The anaesthetist must be informed if the patient is using levobunolol.

If necessary during surgery, the effects of  $\beta$ -adrenergic blocking agents may be reversed by sufficient doses of such agonists as isoprenaline, dopamine, dobutamine or noradrenaline acid tartrate (see Overdosage).

**Diabetes Mellitus:**  $\beta$ -adrenergic blocking agents should be administered with caution to patients subject to spontaneous hypoglycaemia or to diabetic patients (especially those with labile diabetes) who are receiving insulin or oral hypoglycaemic agents.  $\beta$ -adrenergic blocking agents may mask the signs and symptoms of acute hypoglycaemia.

**Hyperthyroidism/Thyrotoxicosis:**  $\beta$ -adrenergic blocking agents may mask certain clinical signs (e.g. tachycardia) of hyperthyroidism. Patients suspected of developing thyrotoxicosis should be managed carefully to avoid abrupt withdrawal of  $\beta$ -adrenergic blocking agents which might precipitate a thyroid storm.

**Metabisulfite Sensitivity:** Contains sodium metabisulfite, a sulfite which may cause allergic-type reactions including anaphylactic symptoms and life-threatening or less severe asthmatic episodes in certain susceptible people. The overall prevalence of sulfite sensitivity in the general population is unknown and probably low. Sulfite sensitivity is seen more frequently in asthmatic rather than in non-asthmatic people.

**Muscle Weakness:**  $\beta$ -adrenergic blockade has been reported to potentiate muscle weakness consistent with certain myasthenic symptoms (e.g. diplopia, ptosis and generalised weakness).

**Risk of anaphylactic reaction:** While taking  $\beta$  blockers, patients with a history of atopy or a history of severe anaphylactic reactions to a variety of allergens may be more reactive to repeated challenge, either accidental, diagnostic or therapeutic. Such patients may be unresponsive to the usual doses of adrenaline used to treat allergic reactions.

**Corneal diseases:** Ophthalmic beta-blockers may induce dryness of eyes. Patients with corneal diseases should be treated with caution.

**Choroidal detachment:** Choroidal detachment after filtration procedures has been reported with the administration of aqueous suppressant therapy (e.g., timolol).

**Other beta-blocking agents:** Caution should be exercised when used concomitantly with systemic beta-andrenergic blocking agents because of the potential for additive effects on systemic beta-blockage. The response of these patients should be closely observed. The use of two topical beta-adrenergic blocking agents is not recommended.

### ***Pregnancy and Lactation***

Pregnancy Category C.

Beta adrenergic blocking agents may cause pharmacological effects of beta-blockade (e.g. bradycardia, hypotension, respiratory distress and hypoglycaemia) in the fetus and newborn infant. During the latter stages of pregnancy and birth, these drugs should be given only after weighing the needs of the mother against the risk to the fetus. If BETAGAN<sup>®</sup> is administered until delivery, the neonate should be carefully monitored during the first days of life.

There are no adequate and well-controlled studies in pregnant women. BETAGAN<sup>®</sup> eye drops should not be used during pregnancy unless clearly necessary.

It is not known whether the drug is excreted in human milk. Systemic  $\beta$ -blockers and topical timolol maleate are known to be excreted in human milk. Caution should be exercised when BETAGAN<sup>®</sup> eye drops are administered to a nursing woman.

### ***Carcinogenesis, Mutagenesis, Impairment of Fertility***

In a lifetime study of mice there were statistically significant ( $p \leq 0.05$ ) increases in the incidence of benign leiomyomas in female mice at 200 mg/kg/day (14,000 times the maximum recommended human dose for glaucoma), but not at 12 or 50 mg/kg/day (850 and 3,500 times the human dose). In a two-year oral study of levobunolol HCl in rats there was a statistically significant ( $p \leq 0.05$ ) increase in the incidence of hepatomas in male rats administered 12,800 times the recommended human dose for glaucoma. Similar differences were not observed in rats administered oral doses equivalent to 350 times to 2,000 times the recommended human dose for glaucoma.

Levobunolol did not show evidence of mutagenic activity in a battery of microbiological and mammalian *in vitro* and *in vivo* assays. Reproduction and fertility studies in rats showed no adverse effects on male or female fertility at doses up to 1,800 times the recommended human dose for glaucoma.

### ***Effects on Ability to Drive and Use Machines***

As BETAGAN<sup>®</sup> eye drops may cause transient blurring, fatigue and/or drowsiness on instillation, caution is required with the use of hazardous machinery or driving, which are not recommended unless symptoms have cleared.

### **ADVERSE EFFECTS**

The following adverse effects have been reported rarely with the use of BETAGAN<sup>®</sup> eye drops: iridocyclitis, headache, transient ataxia, dizziness, lethargy, urticaria and pruritus.

Decreased corneal sensitivity has been noted in a small number of patients. Although levobunolol has minimal membrane-stabilising activity, there remains the possibility of decreased corneal sensitivity after prolonged use.

### ***Clinical Studies Experience***

Frequency categories: very common ( $\geq 1/10$ ); common ( $\geq 1/100$  to  $< 1/10$ ); uncommon ( $\geq 1/1,000$  to  $\leq 1/100$ ); rare ( $\geq 1/10,000$  to  $\leq 1/1,000$ ); very rare ( $\leq 1/10,000$ ), not known (cannot be estimated from available data).

### Eye Disorders

Very Common: Eye irritation, Eye pain

Common: Blepharitis, Conjunctivitis

### ***Postmarketing Experience: Levobunolol hydrochloride***

The following adverse reactions have been identified during postmarketing use of levobunolol eye drops in clinical practice. Because postmarketing reporting of these reactions is voluntary and from a population of uncertain size, it is not always possible to reliably estimate the frequency of these reactions.

### Eye Disorders

Conjunctival/Ocular hyperemia, Conjunctivitis allergic, Corneal reflex decreased, Eye discharge, Eye/Eyelid edema, Eye/Eyelids pruritus, Keratitis, Lacrimation increased, Punctate keratitis, Vision blurred

### General Disorders and Administration Site Conditions

Face edema, Fatigue/Asthenia

### Nervous System Disorders

Confusion, Insomnia, Somnolence

### Psychiatric Disorders

Depression

### Cardiac Disorders

Atrioventricular block, Bradycardia, Palpitations, Syncope

### Vascular Disorders

Hypotension, Raynaud's phenomenon

### Respiratory, Thoracic, and Mediastinal Disorders

Asthma, Dyspnea, Nasal discomfort, Throat irritation

### Gastrointestinal Disorders

Nausea

### Skin and Subcutaneous Tissue Disorders

Dermatitis contact (including allergic contact dermatitis), Erythema of eyelid, Eyelid eczema, Lichenoid keratosis, Rash, Skin exfoliation,

### ***Adverse Drug Reactions – Other Ophthalmic Beta-blockers***

The following additional adverse reactions have been reported with ophthalmic use of  $\beta_1$  and  $\beta_2$  (non-selective) adrenergic blocking agents:

### Eye Disorders

Choroidal detachment following filtration surgery (see Warnings and Precautions), Corneal erosion, Diplopia, Dry eye, Ptosis, Visual disturbances including refractive changes (due to withdrawal of miotic therapy in some cases)

#### Immune System Disorders

Anaphylaxis, Systemic allergic reactions including angioedema

#### Metabolism and Nutrition Disorders

Hypoglycaemia, Masked symptoms of hypoglycaemia in insulin-dependent diabetics (see Warnings and Precautions)

#### Psychiatric Disorders

I, Memory loss, Nervousness, Nightmares

#### Nervous System Disorders

Cerebral ischemia, Cerebrovascular accident, Increases in signs and symptoms of myasthenia gravis, Paresthesia.

#### Cardiac Disorders

Arrhythmia, Heart block, Cerebral vascular accident. Cerebral ischemia, Cardiac arrest, Cardiac failure, Chest pain, Congestive heart failure, Edema.

#### Vascular Disorders

Cold hands and feet

#### Respiratory, Thoracic, and Mediastinal Disorders

Bronchospasm (predominantly in patients with pre-existing bronchospastic disease), Cough, Respiratory failure (predominantly in patients with pre-existing bronchospastic disease), Shortness of breath

#### Gastrointestinal Disorders

Abdominal pain upper, Diarrhea, Dysgeusia, Dry mouth, Dyspepsia, Vomiting.

#### Skin and Subcutaneous Tissue Disorders

Alopecia, Psoriasiform rash or exacerbation of psoriasis, Hypersensitivity including localised and generalised rash.

#### Musculoskeletal and Connective Tissue Disorders

Arthropathy, Myalgia

#### Reproductive System and Breast Disorders

Decreased libido, Sexual dysfunction

#### General Disorders and Administration Site Conditions

Thirst

Other reactions associated with the oral use of non-selective adrenergic blocking agents should be considered potential effects with ophthalmic use of these agents.

### **INTERACTIONS**

BETAGAN<sup>®</sup> eye drops should be used with caution in patients who are receiving a  $\beta$ -adrenergic receptor blocking agent orally, because of the potential for additive effects on systemic  $\beta$ -blockade and on intraocular pressure.

Although BETAGAN<sup>®</sup> eye drops used alone have little or no effect on pupil size, mydriasis resulting from concomitant use of BETAGAN<sup>®</sup> eye drops and mydriatic agents such as adrenaline may occur.

Close observation of the patient is recommended when a  $\beta$ -blocker is administered to patients receiving catecholamine-depleting drugs such as reserpine, because of possible additive effects and the production of hypotension and/or marked bradycardia, which may produce vertigo, syncope or postural hypotension.

There is potential for additive effects resulting in hypotension, and/or marked bradycardia when eye drops with levobunolol are administered concomitantly with oral calcium channel blockers, beta-blocking agents, anti-arrhythmics (including amiodarone) digitalis glycosides or parasympathomimetics.

Patients receiving  $\beta$ -adrenergic blocking agents along with either oral or intravenous calcium antagonists should be monitored for possible atrioventricular conduction disturbances, left ventricular failure and hypotension. In patients with impaired cardiac function, simultaneous use should be avoided altogether.

The concomitant use of  $\beta$ -adrenergic blocking agents with digitalis may have additive effects on prolonging atrioventricular conduction time. Phenothiazine-related compounds and  $\beta$ -adrenergic blocking agents may have additive hypotensive effects due to the inhibition of each other's metabolism.

Beta blockers may increase the hypoglycaemic effect of antidiabetic agents. Beta blockers can mask the signs and symptoms of hypoglycaemia.

Concomitant use of a beta blocker with anaesthetic drugs may attenuate compensatory tachycardia and increase the risk of hypotension. The anaesthetist must therefore be informed if the patient is taking levobunolol.

## **OVERDOSAGE**

No data are available regarding overdosage in humans. Should accidental ocular overdosage occur, flush eye(s) with water or normal saline. If accidentally ingested, efforts to decrease further absorption may be appropriate (gastric lavage).

The most common signs and symptoms to be expected with overdosage of a systemic  $\beta$ -adrenergic blocking agent are symptomatic bradycardia, hypotension, bronchospasm and acute cardiac failure. Should these symptoms occur, discontinue BETAGAN<sup>®</sup> eye drops and initiate appropriate supportive therapy. The following supportive measures should be considered:

1. **Symptomatic bradycardia:** Use atropine sulfate intravenously in a dosage of 0.25 mg to 2 mg to induce vagal blockade. If bradycardia persists, intravenous isoprenaline hydrochloride should be administered cautiously. In refractory cases the use of transvenous cardiac pacemaker should be considered.
2. **Hypotension:** Use sympathomimetic pressor drug therapy, such as dopamine, dobutamine or noradrenaline acid tartrate. In refractory cases the use of glucagon hydrochloride may be useful.

3. **Bronchospasm:** Use isoprenaline hydrochloride. Additional therapy with aminophylline may be considered.
4. **Acute cardiac failure:** Conventional therapy with digitalis, diuretics and oxygen should be instituted immediately. In refractory cases the use of intravenous aminophylline is suggested. This may be followed, if necessary, by glucagon hydrochloride which may be useful.
5. **Heart block (second or third degree):** Use isoprenaline hydrochloride or a transvenous pacemaker.

### **PHARMACEUTICAL PRECAUTIONS**

To avoid contamination of the solution, keep container tightly closed. Do not touch dropper tip to any surface. Contents are sterile if seal is intact.

Shelf life: 24 months  
Storage: Store below 25°C.  
Protect from light and excessive heat.

Discard unused contents 4 weeks after opening.

### **MEDICINE CLASSIFICATION**

Prescription Medicine

### **PACKAGE QUANTITIES**

5 mL dropper bottles

### **FURTHER INFORMATION**

#### ***Excipients***

PRESERVATIVE: benzalkonium chloride

INACTIVES: polyvinyl alcohol (LIQUIFILM<sup>®</sup>), sodium metabisulfite, disodium edetate, sodium phosphate dibasic, potassium phosphate, sodium chloride, purified water and hydrochloric acid or sodium hydroxide to adjust pH.

#### ***Clinical trials***

In several controlled clinical studies of four years duration, IOP was well-controlled in the majority of subjects treated with 0.5% levobunolol HCl b.i.d, with annual retention rates of over 80%. The mean IOP decrease from baseline was between 5.8 mmHg and 7.8 mmHg. A total of 72 subjects remained on this agent over the entire four years treatment. No significant effects on pupil size, tear production or corneal sensitivity was observed in any of these studies. BETAGAN<sup>®</sup> eye drops at the concentrations tested, when applied topically, decreased heart rate and blood pressure in some patients. Efficacy was at least comparable to that of timolol over the entire study period.

In clinical trials the use of BETAGAN<sup>®</sup> eye drops has been associated with transient ocular burning and stinging in about 1 in 3 patients, and blepharoconjunctivitis in about 1 in 20 patients. Decreases in heart rate and blood pressure have been reported (see Contraindications and Warnings and Precautions).

**NAME AND ADDRESS**

Allergan New Zealand Ltd  
Corner of Manu Tapu Drive and  
Joseph Hammond Place  
Auckland International Airport  
Mangere AUCKLAND

Toll free telephone: 0800 659 912
